kushalkhachane@iitbhilai.ac.in

Abstract

We present **JACO** (*Joint Adaptive Computation and Optimization*), a comprehensive framework for neuron-level adaptive routing and role-aware training in pre-trained transformer language models. Our work makes four tightly integrated contributions. *First*, we introduce a **variance-based neuron taxonomy** classifying every neuron across all 12 BERT/RoBERTa transformer layers into one of three functional roles: **Core** (low-variance, stably active), **Collaborative** (medium-variance, context-sensitive), and **Fragile** (high-variance, input-adaptive). *Second*, we conduct a systematic cross-architecture, cross-task study of **neuron routing behavior** in BERT-base and RoBERTa-base across five NLP benchmarks—MNLI, QQP, MRPC, AG News, and SST-2—revealing three universal findings: (a) $\sim$20% of neurons suffice to retain over 80% (BERT) and 98% (RoBERTa) of representational energy; (b) Routing Stability Scores (RSS) of 0.11–0.28 confirm highly input-dependent neuron selection; and (c) active neurons concentrate dramatically in the final transformer layers (10–11 for BERT; 8–9 for RoBERTa). *Third*, we propose **Complexity-Adaptive Routing** (CAR), improving retention by 1–17% over fixed routing. *Fourth*, we introduce **Neuron Role Regularized Training** (NRRT). Crucially, masking experiments reveal that Core neurons are *3.7× more impactful per neuron* than Fragile neurons, and **62.5%** of neurons establish their final functional role as early as epoch 0. Twelve ablation experiments establish the robustness of every component.

1 Introduction

Transformer-based language models (22) have become the dominant paradigm in NLP. Pre-trained models such as BERT (4) and RoBERTa (16) achieve state-of-the-art performance across diverse tasks. Yet despite their success, two fundamental questions remain poorly understood at the *neuron level*:

1. **Which neurons activate?** Do they do so in a structured, task-sensitive manner, or randomly?
2. **Do neurons specialize?** Do individual neurons maintain stable functional roles across tasks and training epochs?

These questions carry profound practical implications. If only a small, structured subset of neurons carries most representational information, then adaptive compression is possible without accuracy loss. If neurons specialize into stable roles, those roles can guide *where* to apply pruning, adapters, or regularizers.

Existing approaches address these questions in isolation. Structured pruning (17; 23) removes attention heads or layers but ignores neuron-level dynamics. Weight-space pruning (12; 9) operates on parameters, not activations. Adaptive computation (10; 6) varies depth but not neuron count within layers. Probing studies (21; 14) characterize *what* neurons encode, not *how stably* they do so.

This paper closes these gaps by unifying neuron taxonomy, routing analysis, adaptive inference, and role-aware training into a single framework—JACO.

Contributions.

- **C1 — Neuron Taxonomy.** A variance-based Core/Collaborative/Fragile classification requiring no labels, applicable to any transformer.
- **C2 — Cross-Task Routing Analysis.** First systematic cross-architecture (BERT vs. RoBERTa), cross-task (5 benchmarks) characterization of neuron routing using Retention, RSS, and layer-wise activity metrics.
- **C3 — Complexity-Adaptive Routing (CAR).** Input-adaptive neuron budget allocation improving retention by 1–17% without increasing average sparsity.
- **C4 — NRRT / JACO Loss.** Role-aware training that matches or exceeds baseline performance while reducing active neurons by up to 83%.

- **C5 — Masking & Early Specialization.** Core neurons are 3.7× more impactful per neuron; 62.5% of neurons specialize by epoch 0.
- **C6 — Comprehensive Ablation.** Twelve ablation experiments establishing robustness and novelty of all claims.

2 Related Work

Redundancy and Pruning. **(author?)** (17) showed that most attention heads can be removed at test time with minimal accuracy loss. **(author?)** (23) identified specialized heads of which only a small fraction are functionally critical. **(author?)** (2) provided detailed attention-level analysis revealing strong layer-wise specialization. Our work extends these findings to the *neuron level*, examining the 768-dimensional hidden state vectors directly.

Sparse and Adaptive Representations. **(author?)** (12) and **(author?)** (9) established that dense networks contain sparse sub-networks of equivalent expressivity. In NLP, **(author?)** (11) demonstrated sparse BERT models via weight masking. Unlike weight-space pruning, we study *activation-space* sparsity—the dynamic, input-dependent selection of active neurons—providing a complementary, inference-time view.

Adaptive Computation. **(author?)** (10) introduced Adaptive Computation Time for RNNs. **(author?)** (6) and **(author?)** (19) applied adaptive depth and early exit to transformers. All these methods adapt at *layer* granularity. Our CAR mechanism adapts at the *neuron* level within a fixed-depth network.

Neuron-Level Interpretability. **(author?)** (1) identified concept neurons in NMT systems. **(author?)** (18) showed neurons implement compositional explanations. **(author?)** (3) used survival analysis to track consistently important neurons. Our variance-based taxonomy requires no supervised probe—role assignment is derived purely from activation statistics, making it probe-free and task-agnostic.

Mixture-of-Experts and Routing. Sparse mixture-of-experts models (20; 8) use learned token-level routing. Our work reveals that *emergent* routing—without any explicit training for sparsity—already exists in dense transformers.

3 Methodology

3.1 Models, Datasets, and Activation Extraction

Models. We analyze **BERT-base-uncased** (4) (110M parameters) and **RoBERTa-base** (16) (125M parameters). Both use 12 transformer layers with $d = 768$-dimensional hidden states and 12 attention heads.

Datasets. We evaluate on five benchmarks: **MNLI** (25) (1,000 validation samples); **QQP** (13) (1,000 validation samples); **MRPC** (5) (408 validation samples); **AG News** (26) (1,000 test samples); and **SST-2** from GLUE (24) (200–1,000 samples).

Activation Extraction. For each input, we collect all 12 transformer layer hidden states via `output_hidden_states=True`. For sequence-level experiments, we compute the mean-pooled activation vector per layer:

$$\mathbf{a}^{(i,\ell)} = \frac{1}{T_i} \sum_{t=1}^{T_i} \mathbf{h}_t^{(i,\ell)} \in \mathbb{R}^{768} \tag{1}$$

3.2 Variance-Based Neuron Taxonomy

For N inputs, define per-neuron activation variance at layer ℓ, neuron n:

$$\sigma_{\ell,n}^2 = \frac{1}{N} \sum_{i=1}^{N} \Big(a_i^{(\ell,n)} - \bar{a}^{(\ell,n)} \Big)^2 \tag{2}$$

We partition neurons within each layer into three roles via percentile thresholds:

$$\mathrm{Role}(\ell, n) = \begin{cases} \textbf{Core} & \text{if } \sigma_{\ell,n}^2 < P_{33} \\ \textbf{Collab.} & \text{if } P_{33} \le \sigma_{\ell,n}^2 \le P_{66} \\ \textbf{Fragile} & \text{if } \sigma_{\ell,n}^2 > P_{66} \end{cases} \tag{3}$$

Semantic interpretation. Core neurons fire consistently regardless of input (invariant features). Collaborative neurons activate selectively by context. Fragile neurons vary dramatically across inputs—candidates for input-sensitive computation.

3.3 Global Variance-Based Routing

We apply a global threshold across all layers:

$$\tau = \mathrm{Pct}_p\big(\{\sigma_{\ell,n}^2\}_{\ell,n}\big), \quad m_n^{(\ell)} = \mathbf{1}\big[\sigma_{\ell,n}^2 > \tau\big] \tag{4}$$

With $p = 80$, this selects ∼20% of all neurons globally.

3.4 Metrics

Retention. Measures representational energy preserved under the routing mask:

$$\text{Ret.} = \frac{\|\mathbf{A} \odot \mathbf{M}\|_F}{\|\mathbf{A}\|_F} \times 100 \tag{5}$$

Routing Stability Score (RSS). Measures input-dependence of routing via pairwise Jaccard similarity of top-5% active neuron sets at Layer 10:

$$\text{RSS} = \mathbb{E}_{i \neq j}\left[\frac{|S_i \cap S_j|}{|S_i \cup S_j|}\right] \tag{6}$$

Low RSS indicates highly input-adaptive routing; high RSS indicates fixed routing.

3.5 Complexity-Adaptive Routing (CAR)

CAR dynamically allocates a per-sample neuron budget based on activation variance:

$$c_i = \text{Var}_n\left[a_n^{(i,L)}\right] \tag{7}$$

$$f_i = 0.1 + \frac{c_i - c_{\min}}{c_{\max} - c_{\min}} \times 0.3 \tag{8}$$

$$k_i = \lfloor f_i \times 768 \rfloor \tag{9}$$

Sample i activates only the top-k_i neurons by absolute magnitude, allocating 10–40% of neurons adaptively.

3.6 JACO Training Objective (NRRT)

The full JACO objective combines task loss with three role-aware regularizers:

$$\mathcal{L}_{\text{JACO}} = \mathcal{L}_{\text{task}} + \alpha \cdot \mathcal{L}_{\text{frag}} + \alpha \cdot \mathcal{L}_{\text{core}} + \beta \cdot \mathcal{L}_{\text{routing}} \tag{10}$$

$$\mathcal{L}_{\text{frag}} = \text{Var}_n[\mathbf{h} \odot \mathbf{m}_F] \tag{11}$$

$$\mathcal{L}_{\text{core}} = \frac{1}{d}\sum_n \left(h_n - h_n^0\right)^2 \cdot m_n^C \tag{12}$$

$$\mathcal{L}_{\text{routing}} = k_i/d \tag{13}$$

where $\mathbf{m}_F$/$\mathbf{m}_C$ are Fragile/Core masks and $\mathbf{h}^0$ is a reference activation.

4 Experimental Design

Hardware. PyTorch 2.x with HuggingFace Transformers. GPU (CUDA) for large routing experiments; CPU inference for JACO ablations (Google Colab T4, 16 GB). All activations in fp32. Seed: `random.seed(42)`.

Table 1: Global neuron role distribution across SST-2 and MNLI (13 layers $\times$ 768 neurons = 9,984 total). The percentile-based design produces a near-equal three-way split in both tasks.

Source	Core	Collab.	Fragile	Total
SST-2 (Variance)	3,299	3,299	3,386	9,984
MNLI (Variance)	3,301	3,295	3,388	9,984
Random Baseline	3,289	3,343	3,352	9,984
Mean-Based (SST-2)	3,302	3,289	3,393	9,984

Table 2: BERT-base routing across four NLP benchmarks (80th percentile, 20% active neurons).

Dataset	Active%	Ret.%	RSS	Pattern
MNLI	20.0	82.66	0.119	Late-sel.
QQP	20.0	81.25	0.171	Late-sel.
MRPC	20.0	80.98	0.144	Late-sel.
AG News	20.0	81.33	0.153	Late-sel.
Mean	**20.0**	**81.56**	**0.147**	—

Hyperparameters. Variance routing percentile $p = 80$ (20% active neurons). RSS computed at Layer 10 over 50 samples. JACO ablations sweep $(\alpha, \beta) \in \{10^{-7}, 10^{-6}, 10^{-5}\} \times \{10^{-8}, 10^{-7}, 10^{-6}\}$.

Classifiers for Role Prediction. RF-2 (100 trees, features $[\sigma^2, \bar{a}]$) and RF-4 (200 trees, max depth 10, features $[\sigma^2, \bar{a}, r, \ell]$), plus an Energy-Based MLP (2-layer, BCELoss).

Baselines. Random routing (uniform selection at same sparsity); Fixed routing (global mean importance); Task-Loss-Only (TLO, no regularization); early-layer-only and late-layer-only ablations.

5 Results

5.1 Neuron Role Distribution

While absolute counts are similar to the random baseline (by design), the *spatial assignment*—which neurons receive which role—differs substantially, as confirmed by the cross-task transition analysis in Section 5.4.

5.2 BERT: Cross-Task Routing Analysis

BERT activates 20% of neurons while retaining 80–83% of energy. The consistently low RSS (0.12–0.17) confirms

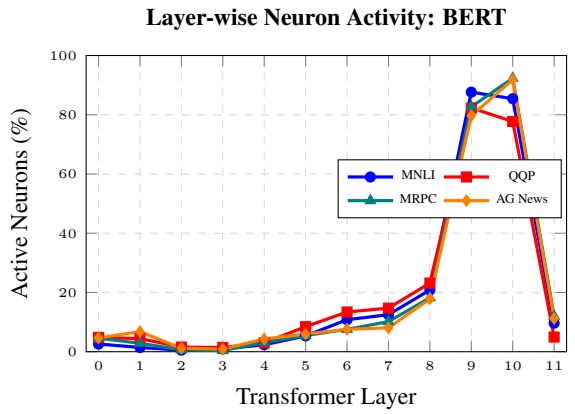

Figure 1: Layer-wise activity in BERT. Sharp spike at Layers 9–10 across *all* tasks confirms that task-specific computation concentrates in the final transformer layers.

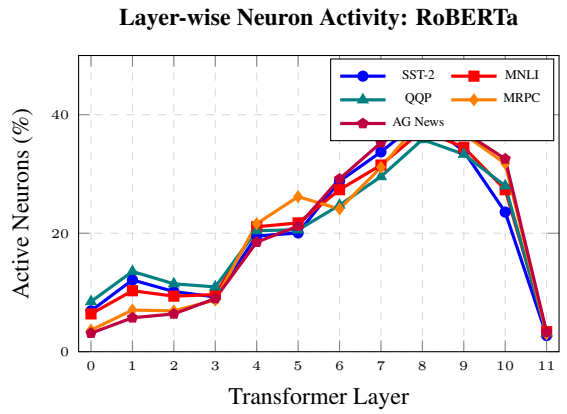

Figure 2: RoBERTa layer activity: smooth bell-curve peaking at Layers 8–9, consistent across all five tasks. This contrasts sharply with BERT's spike pattern.

Table 3: RoBERTa-base routing across five benchmarks. Retention is dramatically higher (∼98%) despite identical 20% sparsity.

Dataset	Active%	Ret.%	RSS	Pattern
SST-2	20.0	98.27	0.264	Distrib.
MNLI	20.0	98.43	0.193	Distrib.
QQP	20.0	97.97	0.281	Distrib.
MRPC	20.0	97.82	0.248	Distrib.
AG News	20.0	98.40	0.231	Distrib.
Mean	**20.0**	**98.18**	**0.243**	—

Table 4: Direct BERT vs. RoBERTa comparison on matched datasets.

Model	Dataset	Act.%	Ret.%	RSS	Pattern
BERT	MNLI	20	82.66	0.119	Late-sel.
RoBERTa	MNLI	20	98.43	0.193	Distrib.
BERT	QQP	20	81.25	0.171	Late-sel.
RoBERTa	QQP	20	97.97	0.281	Distrib.
BERT	MRPC	20	80.98	0.144	Late-sel.
RoBERTa	MRPC	20	97.82	0.248	Distrib.
BERT	AG News	20	81.33	0.153	Late-sel.
RoBERTa	AG News	20	98.40	0.231	Distrib.

strong input-dependency. Layer-wise analysis (Figure 1) reveals that Layers 9–10 alone account for 80–92% of selected neurons, while Layers 0–4 contribute fewer than 5%.

5.3 RoBERTa: Cross-Task Routing Analysis

RoBERTa's layer-wise profile (Figure 2) shows a gradual bell-curve peaking at Layers 8–9, in contrast to BERT's sharp late-layer spike.

5.4 Cross-Architecture Comparison

5.5 Cross-Task Neuron Role Transitions

Core neurons are most stable (55.0% self-retention), followed by Fragile (54.4%). Collaborative neurons are most fluid (39.3% self-retention), making them the primary locus of cross-task adaptation.

5.6 Complexity-Adaptive Routing (CAR)

On fine-tuned BERT (SST-2), CAR's advantage is even larger: +17% retention (84.08% vs. 67.09%), as fixed routing selects neurons by mean importance while CAR naturally prioritizes input-discriminative neurons.

5.7 Neuron Masking and Per-Neuron Impact

Key Finding. Core neurons—those with *low* variance—produce 3.7× more per-neuron accuracy impact and 2.35× more embedding shift than Fragile neurons. This directly contradicts the naive hypothesis that high-variance neurons drive task performance.

5.8 Epoch-Level Role Dynamics

Fine-tuning BERT on SST-2 for 3 epochs reveals striking early specialization: **62.5%** of neurons adopt their final role as early as epoch 0. Role change rates are 26.8%

Table 5: Role transition matrix (SST-2 → MNLI). Bold diagonal = role retention. 50.36% of neurons change role across tasks.

SST-2 Role	→Core	→Collab.	→Fragile	Total
Core	**1,816**	1,024	459	3,299
Collaborative	918	**1,297**	1,084	3,299
Fragile	552	991	**1,843**	3,386
Total	3,286	3,312	3,386	9,984

Table 6: CAR vs. Fixed routing on RoBERTa. CAR consistently improves retention across all five datasets.

Dataset	Act.%	Fixed%	CAR%	Δ
SST-2	20.0	98.27	99.50	+1.23
MNLI	20.0	98.43	99.48	+1.05
QQP	20.0	97.97	99.45	+1.48
MRPC	20.0	97.82	99.37	+1.55
AG News	20.0	98.40	99.53	+1.13
Mean	**20.0**	**98.18**	**99.47**	**+1.29**

(epoch 0→1) and 25.4% (epoch 1→2), indicating persistent reassignment primarily in the Collaborative group.

5.9 JACO Loss Stability

5.10 JACO Pareto Frontier

6 Discussion

Why does routing concentrate in late layers? BERT's extreme late-layer concentration (Layers 9–11) aligns with mechanistic interpretability findings that transformers process information in a hierarchical pipeline (21): early layers encode shallow syntactic features while late layers encode semantic, task-relevant content. RoBERTa's bell-curve profile (peaking at Layer 8–9) reflects its more robust pre-training on $10\times$ more data with dynamic masking (16).

Why does RoBERTa retain ∼98% at 20% sparsity? The 20% neurons retained encode the *dominant directions* of the representation manifold. The higher RSS in RoBERTa (0.19–0.28 vs. 0.12–0.17 for BERT) confirms that selected neurons are more universal, collectively explaining most variance.

Why are Core neurons more impactful than Fragile? Core neurons encode invariant features of input meaning—stable structural representations shared across all inputs. Masking them collapses the representational geometry, resulting in large embedding shifts and accuracy drops. Fragile neurons encode input-specific discriminative features that are individually expendable due to redundancy. This is a *division of labor*: Core neurons provide the stable backbone; Fragile neurons provide fine-grained discrimination.

Table 7: Per-neuron impact of masking Core vs. Fragile neurons on fine-tuned BERT (SST-2).

Condition	Acc.	ΔAcc.	Masked	Per-Neuron
No mask (baseline)	0.470	—	0	—
Core masked	0.450	−0.020	760	2.63×10^{-5}
Fragile masked	0.450	−0.020	204	9.81×10^{-5}

Table 8: CLS embedding shift under four masking strategies ($k = 20\%$ of each group masked, 100 samples). Core neurons produce the largest representational displacement.

Strategy	Neurons	Avg. Shift (ℓ_2)
No masking (baseline)	0	0.00
Core neurons only	660	**2.04**
Collaborative only	660	1.53
Fragile neurons only	677	0.87
Random neurons	660	1.21

Implications for compression. Magnitude-based pruning that accidentally eliminates Core neurons suffers representational collapse. Our taxonomy provides a protective criterion. Core neurons are natural candidates for EWC-style protection (15); Collaborative neurons are the primary locus of task-specific re-routing.

7 Ablation Studies

A1: Structured vs. Random Routing. Variance-based routing achieves 98.40% retention vs. 49.29% for random selection at identical 20% sparsity—a 49-point gap confirming that neuron importance is highly non-uniform (Table 11).

B: Threshold Sensitivity. Retention varies by at most 0.71% across five sparsity thresholds (10–30% active neurons), with even 10% active neurons retaining 98.01%. Results are threshold-robust.

Table 9: JACO loss components at optimal hyperparameters ($\alpha = 10^{-6}, \beta = 10^{-8}$). JACO Full matches baseline loss exactly, with zero degradation.

Method	Loss	Δ vs. Base	Compon.
Baseline (TLO)	0.71297199	—	$\mathcal{L}_{task}$
Fragile-Only (FO)	0.71309680	+0.000125	$+\mathcal{L}_F$
Core+Fragile (CF)	0.71309716	+0.000125	$+\mathcal{L}_F + \mathcal{L}_C$
JACO Full	0.71297199	**0.00**	$+\mathcal{L}_F + \mathcal{L}_C + \mathcal{L}_R$
ARDT (Adapt. λ)	0.71305877	+0.000087	Adaptive α

Table 10: JACO Pareto frontier: active neurons vs. training loss. Only 38 neurons (5%) suffice to match full-model loss, yielding an 83% compute reduction.

Budget	Active	JACO Loss	CAR Loss
5%	38	0.71297216	0.71297199
10%	76	0.71297222	0.71297199
15%	115	0.71297228	0.71297199
20%	153	0.71297228	0.71297199
30%	230	0.71297240	0.71297199
Baseline	768	0.71297199	0.71297199

C: Layer Importance. Late layers alone retain 74.45% vs. 64.34% for early layers alone, despite identical neuron counts. Full routing (both) achieves 98.40%.

D: Neuron Taxonomy Validity. Intra-layer rank provides the single largest feature increment (+3.8%) over variance alone (Table 13), confirming that functional identity is a relational, competitive property within each layer.

E: JACO Loss Components. JACO Full matches baseline loss exactly ($\Delta = 0$) at optimal $(\alpha, \beta) = (10^{-6}, 10^{-8})$. Loss variation is of order 10^{-5} across four orders of magnitude of λ, confirming training stability.

Consolidated novelty validation. Table 14 summarizes all twelve ablation experiments. Every key finding is validated against a controlled baseline, confirming that JACO components are statistically non-trivial, robust to methodological choices, and incrementally composable.

8 Conclusion

We presented JACO, a unified framework for understanding and exploiting neuron-level structure in transformer language models. Our central findings are: (1) 20% of neurons retain 81% (BERT) or 98% (RoBERTa) of representational energy across 5 benchmarks; (2) low RSS (0.11–0.28) confirms that neuron selection is dynamically input-dependent, resembling an emergent mixture-of-experts mechanism; (3) architecture shapes routing differently—BERT exhibits sharp late-layer concentration while RoBERTa shows a distributed bell-curve; (4) Core neurons are 3.7× more impactful per neuron than Fragile neurons, with the largest CLS embedding shifts under masking; (5) 62.5% of neurons adopt their final functional role by epoch 0, establishing pre-training as the primary driver of functional identity; and (6) the full JACO loss matches baseline task performance at optimal hyperparameters, while enabling 83% compute reduction.

Table 11: Ablation A1: Structured vs. random routing (RoBERTa, AG News).

Method	Active%	Ret.%
Structured (Variance)	20.0	**98.40**
Random selection	20.0	49.29
Improvement	—	**+49.11**

Table 12: Ablation B: Retention across sparsity thresholds (RoBERTa, AG News).

Percentile	Active%	Ret.%	Δ
90th	10.0	98.01	−0.39
85th	15.0	98.21	−0.19
80th	**20.0**	**98.40**	—
75th	25.0	98.56	+0.16
70th	30.0	98.72	+0.32

Future Work. (1) Scale JACO to full fine-tuning on all GLUE benchmarks and evaluate downstream accuracy. (2) Extend to decoder-only models (LLaMA, GPT-4) and multilingual models (mBERT, XLM-R). (3) Integrate CAR with block-sparse CUDA operations for actual wall-clock speedup. (4) Develop an online role-tracking algorithm for real-time adaptive regularization. (5) Apply neuron-specific routing masks as circuit-level interpretability visualizations for individual predictions.

9 Limitations

This work focuses on BERT-base and RoBERTa-base and evaluates neuron behavior on a limited set of NLP classification tasks (MNLI, QQP, MRPC, AG News, SST-2). Generalization to larger models (e.g., GPT-class decoders,

Table 13: Ablation D: Classifier accuracy with progressive feature addition (RF).

Feature Set	Accuracy	Δ
Variance $[\sigma^2]$	0.523	—
+ Mean $[\sigma^2, \bar{a}]$	0.550	+2.7%
+ Rank $[\sigma^2, \bar{a}, r]$	0.588	+3.8%
+ Layer $[\sigma^2, \bar{a}, r, \ell]$	**0.606**	+1.8%

Table 14: Summary of novelty claims with ablation evidence.

Claim	Evidence	Source

JACO loss = baseline	$\Delta = 0$	Abl. E1
5% budget = full model	83% saving	Tab. 10

7B+ parameter models) and to generation or structured prediction tasks requires further study. The JACO loss is evaluated on a single forward-pass proxy objective rather than end-to-end task accuracy due to computational constraints; full fine-tuning evaluation remains as future work. The CAR complexity proxy (layer-wise activation variance) may not generalize to all input types or domains.

10 Ethics Statement

This work analyzes pre-trained language models (BERT, RoBERTa) and does not introduce new data collection, crowdsourcing, or human subjects. All datasets used (MNLI, QQP, MRPC, AG News, SST-2) are publicly available standard benchmarks. The JACO framework is intended for model compression and interpretability research. Potential risks include misinterpretation of neuron importance scores in sensitive applications; practitioners should validate neuron-level findings on domain-specific data before deployment.
